The template started from the **Legrand Orange template**.

The cover page started from the templates in **Latexdraw**.

The syntax highlighting for Solidity has been made by **Sergei Tikhomirov**.

PART 1

1. INTRODUCTION

1.0.1. Introduction

I started my programming journey much later than a lot of my peers. Coding and computers were scary topics best left to child prodigies and other geniuses, so why even both I reasoned. Nevertheless, following my first year of undergrad I landed an internship with my school's Physics department. Little did I know the internship was about 1% physics, and 99% learning C++. My professor worked in low-energy nuclear physics, and his group's experiments generated large amounts of data that needed to be processed. My first introduction with "real" coding was with C++, doing large-scale analysis. I spent my summer switching between online documentation and gedit, the text editor he showed me on my first day. Following this internship, I started to learn a bit of C, and was happy when I found out I could change the colors in Notepad++.

Eventually a friend took pity on me and pointed me out to Visual Studio. I cannot understate how mindblowing things like autocomplete, jump to definition, and intelligent syntax highlighting was to me after months of default Notepad++. I didn't have to spend time searching through a code base to find a type definition, didn't have to run gcc to find out I had forgotten a semilolon on line 64, etc. I wondered how these features worked, but understanding seemed beyond my grasp. If I'm struggling to even write code, then code that can "understand" other code has to be on some elevated plane of complexity.

I continued on through my classes, learning lots of theory, but not coding very much. Eventually I stumbled upon The Primeagen by accident on YouTube one day. It's hard to put into words how much he changed my outlook on programming and CS for the better. After months of listening to him shill for Neovim and Rust, I decided to spend a summer learning the language and editor. These things scared me, but I had finally gotten over this fear and just decided to try my best and see where I ended up.

I *cannot* understate what a great decision this was. Coding has never been more fun. After reading through the Rust book, I set out to complete the 2022 Advent of Code calendar. Working through those exercises (and sometimes referring to Reddit for help), I slowly figured things out. After a few weeks, I was comfortable enough to start making small modifications to the Lua configuration I had copied from Prime's setup video. I finished Advent of Code, and started looking for a larger project to work on.

I eventually stumbled onto **asm-lsp**, an open-source assembly LSP written in Rust. The project had hover support for instructions, but that was about it. I found a small `// TODO` comment in the source code, and decide to take a look. After an hour of hopping around the project with the help of the Rust LSP, I thought I had an idea of how to solve the problem. I opened a pull request, and to my surprise it was accepted. I started digging into the code a bit more, and found another thing to fix. And then I found a feature to add. And then another. And another. Over the course of a few months, I got very comfortable with the LSP's code, and in turn also found myself fairly comfortable with the LSP protocol. Working on the project had demysitified the "magic" code that understood code, and I found myself enjoying the rabbit hole I had unwitteningly dived down.

This learning journey was incredibly valuable to me, and I'd like to help others discover this magic.

1.0.2. What is this book?

As the title suggests, this book walks you through building an LSP server for x86-64 assembly. It won't be the most complete LSP server, it won't be the cleanest, but it will be *yours*. We'll start with a basic scaffold and build up from there. So anyways, onto the burning question:

"Why Assembly? Nobody actually codes in that anymore."

Fair enough, almost nobody actually hand rolls assembly anymore. Those damned compiler people have done too good of a job! (If you're interested in compilers though, I can't reccomend Thorsten Ball's **"Writing an Interpreter in Go"** and **"Writing a Compiler in Go"** enough. Both are incredibly well done and helped motivate me to write this book.) But in all seriousness, I've chosen assembly for its *simplicity*. Assembly is simple enough that the majority of one's effort can be spent learning the main item, LSPs! Assembly's flat structure makes things just simple enough so that lots of features can be doable without weeks of studying a specific language's features. The obvious alternative is to use a toy language, which in my opinion sucks all the fun out. Building things for the sake of building is great, but creating something useful along the way is better! All you really have to know is that there are instructions and registers. Instructions tell the computer to do something and typically take 0 to 2 arguments. Registers are like tiny variables for the CPU. They vary in size, usually a nice power of 2 from 16 bits and up. Finally there are assembler directives, which basically just tell the assembler to do something, but aren't translated to machine code like instructions are. To be more concrete, here's a simple hello world program written for the GNU Assembler (GAS).

```
1   # gcc -nostdlib -nostartfiles -nodefaultlibs -static hello_lsp.s -o
        hello_lsp && ./hello_lsp
2
3   .data
4
5   .equ    SYSCALL_WRITE, 1
6   .equ    SYSCALL_EXIT, 60
7   .equ    STDOUT, 1
8   .equ    EXIT_SUCCESS, 0
9
10  message:
11      .asciz "Hello, LSP!\n" # Our message to print
12
13  .equ MSG_LEN, . - message # The length of our message
14
15  .global _start
16
17  .text
18
19  _start:
20      # write (1, msg, len(msg))
21      mov $SYSCALL_WRITE, %rax
22      mov $STDOUT, %rdi
23      mov $message, %rsi
24      mov $MSG_LEN, %rdx
25      syscall
26
27      # exit(0)
```

```
28      mov $SYSCALL_EXIT, %rax
29      xor %rdi, %rdi
30      syscall
```

Without going into too much detail, the `.data` directive simply tells the assembler to assemble the following statements into a data subsection. Underneath that, `.equ` works essentially the same as the C preprocessor's `#define`. Finally `.asciz` creates a null terminated C string. We then grab the length of the message. Some data gets moved around so we can make the `write` and `exit` system calls, and that's about it! The specifics can vary depending on architecture and assembler you're using, but most assembly is fairly similar in structure.

We'll start with some general LSP information and project setup. While I won't skip any steps, I'll do my best to speed through the non-LSP parts to keep things interesting. While there's lots to be learned about things like XML parsing, serialization, deserialization, and JSON RPC, I'm not the right person and this isn't the right book to teach those things. After these initial steps, we'll have a working program that can connect to an LSP client, load some relevant information from the disk...and that's about it. But don't despair! The very next thing on our list is to add hover support for instructions and registers. After this feature is in place, we'll sidetrack briefly to add some configuration options for our users (of which there will be many thousands, so we can also practice asking the product manager "but how will this scale?"). Next we'll add autocomplete!

Doing so will require a couple different steps, but this is when things truly start to get fun. When I first added autocomplete to asm-lsp, things really started to click. After autocomplete, we'll add a bunch of cool (but relatively siloed) capabilities.

2. GETTING STARTED

All of the finished code for each chapter can be found in the **book's repo**. With that being said, let's get started!

2.0.1. Dependencies

As with nearly any other Rust project, we can start by creating a new project with cargo: `cargo new assembly-lsp`. We'll add some dependencies next:

- `cargo add crossbeam-channel`
  - Handles sending and receiving data across channels so our LSP server can talk to our editor's LSP client
- `cargo add flexi_logger`
  - Allows for some easy structured logging over `stderr`.
- `cargo add log`
  - Another logging crate we'll use
- `cargo add lsp-server`
  - Handles the majority of LSP-related things for us. This crate lets us focus on features, rather than implementing a spec.
- `cargo add lsp-types`
  - The LSP spec includes a fair number of type defitinitions, which are (unfortunately) in Typescript. This crate provides Rust versions of the spec's types that adhere to the spec.
- `cargo add serde --features derive`
  - This amazing crate is part of nearly every Rust project, including ours too.
- `cargo add serde_json`
  - LSP servers and clients communicate over JSON RPC. Naturally this crate will be of use.

2.0.2. Starting Code

Now that the scaffolding is in place, we can finally get to coding. A great template can be found in the rust-analyzer (the absolutely excellent Rust LSP) **repo**. Their example starts out with some code for the go to definition capability. We'll get there eventually, but our starting point is different. Here's the stripped down code:

```
1  use log::info;
2  use lsp_server::{Connection, ExtractError, Message, Request, RequestId};
3  use lsp_types::{InitializeParams, ServerCapabilities};
4
5  fn main() -> anyhow::Result<()> {
6      // Set up logging. Because `stdio_transport` gets a lock on stdout
       and stdin, we must have our
7      // logging only write out to stderr.
8      flexi_logger::Logger::try_with_str("info")?.start()?;
9
10     info!("Starting assembly-lsp");
11
```

PART 1

```rust
12      // Create the transport. Includes the stdio (stdin and stdout)
        versions but this could
13      // also be implemented to use sockets or HTTP.
14      let (connection, io_threads) = Connection::stdio();
15
16      // Run the server and wait for the two threads to end (typically by
        trigger LSP Exit event).
17      let server_capabilities = serde_json::to_value(&ServerCapabilities {
18          ..Default::default()
19      })
20      .unwrap();
21
22      let initialization_params = connection.initialize(
        server_capabilities)?;
23
24      main_loop(connection, initialization_params)?;
25      io_threads.join()?;
26
27      // Shut down gracefully.
28      info!("Shutting down assembly-lsp");
29      Ok(())
30  }
31
32  fn main_loop(connection: Connection, params: serde_json::Value) ->
        anyhow::Result<()> {
33      let _params: InitializeParams = serde_json::from_value(params).
        unwrap();
34      info!("Entering main loop");
35      for msg in &connection.receiver {
36          eprintln!("got msg: {msg:?}");
37          match msg {
38              Message::Request(req) => {
39                  if connection.handle_shutdown(&req)? {
40                      return Ok(());
41                  }
42                  info!("Got request: {req:?}");
43              }
44              Message::Response(resp) => {
45                  info!("Got response: {resp:?}");
46              }
47              Message::Notification(notif) => {
48                  info!("Got notification: {notif:?}");
49              }
50          }
51      }
52      Ok(())
53  }
54
55  fn cast_req<R>(req: Request) -> Result<(RequestId, R::Params),
        ExtractError<Request>>
56  where
57      R: lsp_types::request::Request,
58      R::Params: serde::de::DeserializeOwned,
```

9

```
59  {
60      req.extract(R::METHOD)
61  }
```

There's nothing too crazy here, but it'll help to unpack everything briefly. There are two main pieces to this: `main()` and `main_loop()`. `main` will be the first code to run when our server starts. We'll do a lot of setup and configuration in here, before entering our second main block, the `main_loop()`. This portion of the code just spins forever, recieving and (potentially) responding to requests and notifications from the editor's language client. Those who have done any programming with Arduinos will find this pattern to be very familiar. Anyway, let's start from the top! The first thing we do is set up our logging. As the LSP protocol uses `stdout` for client-server communication, we configure our logger to use `stderr`. Next we use the `lsp-server` crate to open a connection between the LSP server (our program) and an LSP Client (likely a text editor).

Next we have an object to specify our server capabilities to the client. If you've taken a look at the **LSP spec**, you probably noticed a large number of capabilities. The great thing about the LSP spec is that we only have to implement the capabilities we want to. From the **docs**:

> "Not every language server can support all features defined by the protocol. LSP therefore provides 'capabilities'. A capability groups a set of language features."

The capabilities are all optional, and if look at the `lsp-types` crate, we can see that every capability-related type is of type `Option<T>`. As the default value for any `Option` type is `None`, we can safely specify the capabilities we care about, and ignore all the others.

With our (currently empty) capabilities defined via `server_capabilities`, we communicate them via the 'initialize' request and receive client's capabilities back in turn. With this handshake out of the way, we then enter the meat of the program, which is just a simple event loop to receive and respond to requests from the client. Rust's pattern matching really shines here, letting us easily break down our server's actions by the type of message its received. Our event loop doesn't do anything besides print out the messages it receives. At this point it would probably be useful to test things out and make sure the program is behaving as expected. While we'd normally just test the things by running the LSP with our editor of choice, for pedagogical purposes it can be useful to see how things work manually. If we run our server from the command line, (with a little help from `sed` we can act as the LSP client and manually enter JSON RPC messages. Starting with

```
1      sed -u -re 's/^(.*)$/\1\r/' | cargo run
```

we should see our program build and then start. Entering

```
1  Content-Length: 85
2
3  {"jsonrpc": "2.0", "method": "initialize", "id": 1, "params": {"capabilities":
      {}}}
```

followed by

```
1  Content-Length: 59
2
3  {"jsonrpc": "2.0", "method": "initialized", "params": {}}
```

will give our server enough information to enter into it's event loop. This isn't a good way to interact with or test the, but it's helpful to peel back the curtain at times and see that this isn't magic. It really is just JSON RPC over `stdout`. We can wrap things up by sending shutdown and exit requests.

```
1  Content-Length: 67
2
3  {"jsonrpc": "2.0", "method": "shutdown", "id": 3, "params": null}
```

followed by

```
1  Content-Length: 54
2
3  {"jsonrpc": "2.0", "method": "exit", "params": null}
```

All of this together:

```
1  $ sed -u -re 's/^(.*)$/\1\r/' | cargo run
2
3  Compiling assembly-lsp v0.1.0 (/home/lillis/projects/LSPBook/assembly-lsp)
4  warning: function `cast_req` is never used
5    --> src/main.rs:55:4
6     |
7  55 | fn cast_req<R>(req: Request) -> Result<(RequestId, R::Params),
      ExtractError<Request>>
8     |       ^^^^^^^^

32
33 {"jsonrpc": "2.0", "method": "exit", "params": null}
34 INFO [assembly_lsp] Shutting down assembly-lsp
35 $
```

Finally, underneath the main loop we have a small helper function `cast_req`. Depending on your experience level with Rust, this function signature may look a little scary, but I promise it's not. Per the LSP spec, the parameters passed along with each request all have distinct types. The trait bounds used in the function's signature simply allows it to take in a request and return the correct parameter type.

11

2.0.3. `LSP to Editor Connection`

Now that most of the boilerplate-y code is in place, let's connect our server to our editor. This process can vary greatly from editor to editor.

I personally use Neovim, and would highly reccomend it to anyone interested in creating their own **Personal Development Environment**. However with it being a very personalized editor, methods for attaching a new LSP can cary greatly depending on one's config. For the purposes of this book however, we want to focus on LSPs, not finding the right ~~incantation~~ set of configuration options to make the two processes connect. I've gone through this process for a few editors, and found Sublime's setup to be the easiest *by far*. I would highly encourage you to set up the LSP in your editor of choice. However, in the interest of having some guaranteed way to test things, I'll go through the sublime setup below. I've included the specific steps I followed on my Ubuntu system, but if that doesn't work I've also provided links to the relevant documentation.

1. Install **Sublime Text** if you don't already have it
   - For me, this was just `sudo apt-get install sublime-text`
2. Install Sublime's **LSP** client
   - Open Sublime
   - Open the command pallet (default is Control+Shift+p)
   - Run `Package Control: Install Package`
   - Select `LSP`
3. Ensure the executable produced for our program can be found on the system `PATH`
4. Configure Sublime to work with our LSP
   - Open the command pallet (default is Control+Shift+p)
   - Run `Package Control: Install Package`
   - Select the **x86 and x86_64 Assembly** package
   - Open `Preferences > Package Settings > LSP > Settings` and add the "`assembly-lsp`" client configuration to the "`clients`":

```
1  {
2      "clients": {
3          "assembly-lsp": {
4              "enabled": true,
5              "command": ["assembly-lsp"],
6              "selector": "source.asm | source.assembly"
7          }
8      }
9  }
```

...And that should be it! We can make sure things are working by opening the project's test file in Sublime and checking the logs (`Tools > LSP > Toggle Log Panel`). We should see the same logs we added earlier, as well as the JSON messages exchanged as part of the protocol. That's all the setup we'll do for now, let's get started on our first feature

PART 1

3. HOVER SUPPORT

The time is now! We're finally adding a real feature to our LSP! We'll start by adding hover support for instructions. A few things need to happen first though, before we see that sweet sweet hover documentation window. First we need some source of information for our instructions. This source needs to be in a fairly organized, regular format fit for parsing. After finding such a source, we then need to write some code to parse and load it into our program. This will require some parsing code (duh), as well as some data structures to represent our information once it's loaded from disk. Finally, we need to trigger every time a hover request comes in from the client, check our relevant data structures, and return any results we find in the right format. Without further ado, let's get started.

3.0.1. Finding an Information Source

The first thing we need is find some kind of data source for the x86_64 instructions. It should be well organized, reasonably convertible to some in-memory data structure, and hopefully actively maintained (many active assembly languages receive regular updates). Lucky for us, such a data source already exists! The open source **Opcodes** repo conveniently has both the x86 and x86_64 instruction sets in an xml file. Let's pull the appropriate file into our project:

```
1  mkdir opcodes && cd opcodes
2  curl https://github.com/Maratyszcza/Opcodes/blob/master/opcodes/x86.xml --
       output x86.xml
```

Our project should look two directories now (ignoring the `target` build directory).

```
1  assembly-lsp
2  |--Cargo.lock
3  |--Cargo.toml
4  |--opcodes
5  |   |--x86.xml
6  |--src
7      |--main.rs
```

Let's take a look inside that new file!

```
1  <?xml version='1.0' encoding='utf-8'?>
2  <InstructionSet name="x86">
3    <Instruction name="AAA" summary="ASCII Adjust After Addition">
4      <InstructionForm gas-name="aaa" go-name="AAA">
5        <Encoding>
6          <Opcode byte="37"/>
7        </Encoding>
8      </InstructionForm>
9    </Instruction>
10   <Instruction name="AAD" summary="ASCII Adjust AX Before Division">
11     <InstructionForm gas-name="aad" go-name="AAD">
12       <Encoding>
13         <Opcode byte="D5"/>
14         <Opcode byte="0A"/>
15       </Encoding>
16     </InstructionForm>
17     <InstructionForm gas-name="aad" go-name="AAD">
18       <Operand type="imm8"/>
```

13

```
19        <Encoding>
20          <Opcode byte="D5"/>
21          <Immediate size="1" value="#0"/>
22        </Encoding>
23      </InstructionForm>
24    </Instruction>
25    <Instruction name="AADD" summary="Atomically ADD">
26    ...
```

It looks like each instruction has its name stored along with a short summary. Nested
inside each `<Instruction ...` there also appears to be one or more instruction forms for
the GNU Assembler (GAS) or the Go Assembler. Each form has some more information
included, such as the opcodes for that form, the different arguments it can take, etc. How
are we going to represent this data inside our program?

3.0.2. Data Structures and Parsing

This calls for a new file! Let's create `src/instruction.rs` and start laying out our data.
Here's a start...

```
1  pub struct Instruction {
2      name: String,
3      summary: String,
4      ...
5  }
```

Those instruction forms seem fairly important, so let's create a struct to represent them
and then store a vector of forms inside each instruction. Given that there are opcode files
for both x86 and x86_64, we should probably put some kind of architecture information
in there as well. Finally, we'll also derive some common methods on these to make our
lives easier down the road.

```
1  #[derive(Debug, Clone, Default)]
2  pub struct Instruction {
3      pub name: String,
4      pub summary: String,
5      pub arch: Option<Arch>,
6      pub forms: Vec<InstructionForm>,
7  }
8
9  #[derive(Debug, Clone, Default)]
10 pub struct InstructionForm {
11     pub gas_name: Option<String>,
12     pub go_name: Option<String>,
13     pub encoding: String,
14     pub operands: Vec<Operand>
15 }
16
17 #[derive(Debug, Clone)]
18 pub struct Operand {
19     pub op_type: OperandType,
20     pub input: bool,
21     pub output: bool,
```

14

```
22  }
23
24  #[allow(non_camel_case_types)]
25  #[derive(Debug, Clone, Copy)]
26  pub enum Arch {
27      x86,
28      x86_64,
29  }
```

Writing out all of the variants for the `OperandType` enum looks really annoying and tedious...luckily I've done it for you! For the sake of brevity, I'll also take this time to introduce some new crates (`cargo add strum` and `cargo add strum_macros` when you have a minutes) to our project. We'll use these dependencies to great effect while parsing and deserializing the `x86.xml` file. Some operand types conflict with Rust's naming rules for its enum variants, so in those cases I've changed the variant name to something reasonably close, and then included the `#[strum(serialize = "<ActualOpTypeHere>")]` macro to make the translation possible. We'll also apply these helpers to our `Arch` enum.

```
1  use strum_macros::{AsRefStr, EnumString};
2
3  ...
4
5  #[allow(non_camel_case_types)]
6  #[derive(Debug, Clone, Copy, EnumString, AsRefStr, Default)]
7  pub enum Arch {
8      #[default]
9      x86,
10     x86_64,
11 }
12
13 #[allow(non_camel_case_types)]
14 #[derive(Debug, Clone, EnumString, AsRefStr)]

3.0.3. Information Loading

Great! Now we have a bunch of data in our xml file, and we have some places to put all that data with our above data structures! Now we just need to actually *put* the data in the structs. Again, we're focusing on LSPs here! I'll spare the reader from what would have most certainly been an eloquent, flowing explanation and instead present the code with a brief explanation after. We'll add a new dependency with `cargo add quick-xml`, and then start with a fresh file **src/populate.rs**, we have...

```rust
/* src/populate.rs */
use crate::instruction::{Operand, OperandType, Instruction,
    InstructionForm};
use std::collections::HashMap;

use std::str;
use std::str::FromStr;

use quick_xml::events::attributes::Attribute;
use quick_xml::events::Event;
use quick_xml::name::QName;
use quick_xml::Reader;

use anyhow::anyhow;
use log::debug;

/// Takes xml file contents and converts it into a Vec<Instruction>
pub fn populate_instructions(xml_contents: &str) -> anyhow::Result<
    HashMap<String, Instruction>> {
    let mut instructions_map = HashMap::<String, Instruction>::new();

    let mut reader = Reader::from_str(xml_contents);
    reader.trim_text(true);

    // instruction and instruction form that are currently under
    construction
    let mut curr_instruction = Instruction::default();
    let mut curr_instruction_form = InstructionForm::default();

    debug!("Parsing XML contents...");
    loop {
        match reader.read_event() {
            // start event
            ------------------------------------------------------------------------

            Ok(Event::Start(ref e)) => {
                match e.name() {
                    QName(b"Instruction") => {
                        // start of a new instruction
                        curr_instruction = Instruction::default();

                        // iterate over the attributes
                        for attr in e.attributes() {
                            let Attribute { key, value } = attr.unwrap();
```

```rust
40                              match str::from_utf8(key.into_inner()).
    unwrap() {
41                                  "name" => unsafe {
42                                      let name = String::from(str::
    from_utf8_unchecked(&value).to_lowercase());
43                                      curr_instruction.name = name;
44                                  },
45                                  "summary" => unsafe {
46                                      curr_instruction.summary =
47                                          String::from(str::
    from_utf8_unchecked(&value));
48                                  },
49                                  _ => {}
50                              }
51                          }
52                      }
53                      QName(b"InstructionForm") => {
54                          // new instruction form
55                          curr_instruction_form = InstructionForm::default
    ();
56
57                          // iterate over the attributes
58                          for attr in e.attributes() {
59                              let Attribute { key, value } = attr.unwrap();
60                              match str::from_utf8(key.into_inner()).
    unwrap() {
61                                  "gas-name" => unsafe {
62                                      curr_instruction_form.gas_name =
63                                          Some(String::from(str::
    from_utf8_unchecked(&value).to_lowercase()));
64                                  },
65                                  "go-name" => unsafe {
66                                      curr_instruction_form.go_name =

       buffer_position(), e),
137         _ => (), // rest of events that we don't consider
138     }
139   }
140
141   Ok(instructions_map)
142 }
```

This is a fair amount of code, but most of it is fairly straightforward. The `quick-xml` crate allows for event-based reading. Each opening `<Instruction name=``...` goes right along with an `Event::Start()` with the reader. Similarly, each closing `</Instruction>` pairs with a corresponding `Event::End()`. The qualified name (`QName()`) allows us to distinguish between events for `Instruction`s, `InstructionForm`s, and other pieces of information. A new `Instruction` struct is created with each starting event, its fields are filled in, and the struct is moved into a `HashMap` on a closing event. The same goes for `InstructionForm`s, except on close the form is appended to the current `Instruction`'s `forms` field.

Those who gave the code a quick glance may have noticed the alarming amount of `unsafe{}` blocks the code uses. Isn't unsafe code bad? Aren't we risking frequent crashes and an unreliable end product? Well, not really. This piece of code runs once (maybe a handful of times once we get further into the project) at startup and that's it. The function's input (our xml file) will rarely or never change. Once everything is working today, we can rest assured that it will also work tomorrow. We could *definitely* write this without any `unsafe{}` blocks by simply replacing `str::from_utf8_unchecked()` with `str::from_utf8()` and handling any errors appropriately. Using the unchecked variant gives a performance boost, however, as the code doesn't check to make sure that the string contains valid UTF-8 first. This boost translates into our server reaching full-functionality faster after starting, which will translate directly into a better user experience. I took the time to measure the two (which you should do for *any* performance work!) and found a definite, albeit small performance boost for the unsafe version. Given that it adds little to no extra complexity, we'll take it!

Potentially dubious performance claims aside, let's continue! Let's take that code we just wrote and put it to use. We'll call this new function in our `main()` function, and then pass the resulting map to `main_loop()` to service requests.

```
1  /* src/main.rs */
2  use std::collections::HashMap;
3
4  use assembly_lsp::{instruction::Instruction, populate::
       populate_instructions};
```

```
5
6   fn main() -> anyhow::Result<()> {
7       ...
8
9       let initialization_params = connection.initialize(
        server_capabilities)?;
10
11      info!("Populating instruction set -> x86...");
12      let xml_conts_x86 = include_str!("../opcodes/x86.xml");
13      let x86_instrs = populate_instructions(xml_conts_x86)?;
14
15      main_loop(connection, initialization_params, x86_instrs)?;
16      io_threads.join()?;
17
18      // Shut down gracefully.
19      info!("Shutting down assembly-lsp");
20      Ok(())
21  }
22
23  fn main_loop(
24      connection: Connection,
25      params: serde_json::Value,
26      x86_instrs: HashMap<String, Instruction>,
27  ) -> anyhow::Result<()> {
28      let _params: InitializeParams = serde_json::from_value(params).
        unwrap();
29      info!("Entering main loop");
30      for msg in &connection.receiver {
31          info!("got msg: {msg:?}");
32          match msg {
33              Message::Request(req) => {
34                  if connection.handle_shutdown(&req)? {
35                      return Ok(());
36                  }
37                  info!("Got request: {req:?}");
38              }
39              Message::Response(resp) => {
40                  info!("Got response: {resp:?}");
41              }
42              Message::Notification(notif) => {
43                  info!("Got notification: {notif:?}");
44              }
45          }
46      }
47      Ok(())
48  }
```

3.0.4. Hover Requests

We're almost there! Our next step is to connect our instruction information in the map and incoming hover requests from our editor. Our first step is to recognize when we're

receiving a hover request:

```
1  /* src/main.rs */
2  fn main_loop(
3      connection: Connection,
4      params: serde_json::Value,
5      x86_instrs: HashMap<String, Instruction>,
6  ) -> anyhow::Result<()> {
7      let _params: InitializeParams = serde_json::from_value(params).
       unwrap();
8      info!("Entering main loop");
9      for msg in &connection.receiver {
10         info!("got msg: {msg:?}");
11         match msg {
12             Message::Request(req) => {
13                 if connection.handle_shutdown(&req)? {
14                     return Ok(());
15                 }
16                 info!("Got request: {req:?}");
17                 if let Ok((id, params)) = cast_req::<HoverRequest>(req) {

18                     info!("{:?}", params);
19                 }
20             }
21             Message::Response(resp) => {
22  ...
```

If you'd like, take a minute to test this! Try initiating hover requests from various points within the sample file. Which fields of the params stay the same? Which change? You may have noted that we don't get a ton of information with each request. Looking at the spec, we can see the following:

```
1  interface HoverParams {
2    textDocument: string; /** The text document's URI in string form */
3    position: { line: uinteger; character: uinteger; };
4  }
```

This matches fairly closely with the type provides by the `lsp_types` crate:

```
1  pub struct HoverParams {
2      pub text_document_position_params: TextDocumentPositionParams,
3      pub work_done_progress_params: WorkDoneProgressParams,
4  }
5
6  pub struct TextDocumentPositionParams {
7      /// The text document.
8      pub text_document: TextDocumentIdentifier,
9
10     /// The position inside the text document.
11     pub position: Position,
12  }
13
14  pub struct TextDocumentIdentifier {
15      pub uri: Url,
16  }
```

```
17
18  pub struct Position {
19      /// Line position in a document (zero-based).
20      pub line: u32,
21      /// Character offset on a line in a document (zero-based).
22      pub character: u32,
23  }
```

We have the cursor's position within the file, and the uri of the file itself. We can start by simply opening the file, going the specified postiion, and seeing what's there. "Hey", you might be thinking, "isn't I/O really slow? I want my LSP to be blazingly fast!". You would be right, but don't worry! We'll transition to a much faster means of accessing document contents later on. But for now, let's create a new `src/lsp.rs` file and add some new functionality! Our project's structure should look like the following now:

```
1   assembly-lsp
2   |--Cargo.lock
3   |--Cargo.toml
4   |--opcodes
5   |   |--x86.xml
6   |--src
7       |--instruction.rs
8       |--lib.rs
9       |--lsp.rs
10      |--main.rs
11      |--populate.rs
```

And our newly created file should be the following:

```
1   /* src/lsp.rs */
2   use std::{fs::File, io::BufRead};
3
4   use lsp_types::TextDocumentPositionParams;
5
6   use anyhow::anyhow;
7
8   /// Find the start and end indices of a word inside the given line
9   pub fn find_word_at_pos(line: &str, col: usize) -> (usize, usize) {
10      let line_ = format!("{} ", line);
11      let is_ident_char = |c: char| c.is_alphanumeric() || c == '_';
12
13      let start = line_
14          .chars()
15          .enumerate()
16          .take(col)
17          .filter(|&(_, c)| !is_ident_char(c))
18          .last()
19          .map(|(i, _)| i + 1)
20          .unwrap_or(0);
21
22      #[allow(clippy::filter_next)]
23      let mut end = line_
24          .chars()
25          .enumerate()
26          .skip(col)
```

24

```
27        .filter(|&(_, c)| !is_ident_char(c));
28
29    let end = end.next();
30    (start, end.map(|(i, _)| i).unwrap_or(col))
31  }
32
33  pub fn get_word_from_file_params(
34      pos_params: &TextDocumentPositionParams,
35  ) -> anyhow::Result<String> {
36      let uri = &pos_params.text_document.uri;
37      let line = pos_params.position.line as usize;
38      let col = pos_params.position.character as usize;
39
40      let filepath = uri.to_file_path();
41      match filepath {
42          Ok(file) => {
43              let file = File::open(file).unwrap_or_else(|_| panic!("
      Couldn't open file -> {}", uri));
44              let buf_reader = std::io::BufReader::new(file);
45
46              let line_conts = buf_reader.lines().nth(line).unwrap().
      unwrap();
47              let (start, end) = find_word_at_pos(&line_conts, col);
48              Ok(String::from(&line_conts[start..end]))
49          }
50          Err(_) => Err(anyhow!("filepath get error")),
51      }
52  }
```

The details here are a bit messy, but the overall picture should be very straightforward.
We'll pass the `TextDocumentPositionParams` object we got as part of our hover request
parameters to `get_word_from_file_params()`. This function will use the params to read
the appropriate file from disk. The relevant line is grabbed, and from there we can use
`find_word_at_pos()` to return whatever "word" is under the cursor. In this case, a word
is simply whatever contiguous alphanumeric characters (and underscores) are under the
cursor. Side note but Rust's support for iterators is really excellent. Now that I've done
my mandatory shilling, let's use our new code! We can check exactly when we receive
a hover request! We can get the word under the cursor for the hover request! We can
search our hashmap of instructions for that word! We can send back...wait, what are we
supposed to send back?

```
1  /* src/main.rs */
2  use std::collections::HashMap;
3
4  use assembly_lsp::{
5      instruction::Instruction, lsp::get_word_from_file_params, populate::
      populate_instructions,
6  };
7  use log::info;
8  use lsp_server::{Connection, ExtractError, Message, Request, RequestId,
      Reponse};
9  use lsp_types::{
10     request::HoverRequest, Hover, HoverContents, InitializeParams,
```

```
        MarkupContent, MarkupKind,
11       ServerCapabilities,
12  };
13
14
15  fn main() -> anyhow::Result<()> {
16  ...
17
18  fn main_loop(
19      connection: Connection,
20      params: serde_json::Value,
21      x86_instrs: HashMap<String, Instruction>,
22  ) -> anyhow::Result<()> {
23      let _params: InitializeParams = serde_json::from_value(params).
    unwrap();
24      info!("Entering main loop");
25      for msg in &connection.receiver {
26          info!("got msg: {msg:?}");
27          match msg {
28              Message::Request(req) => {
29                  if connection.handle_shutdown(&req)? {
30                      return Ok(());
31                  }
32                  info!("Got request: {req:?}");
33                  if let Ok((id, params)) = cast_req::<HoverRequest>(req) {

34                      if let Ok(word) =
35                          get_word_from_file_params(&params.
    text_document_position_params)
36                      {
37                          match x86_instrs.get(&word) {
38                              Some(instr) => {
39                                  // what now?
40                              },
41                              None => {
42                                  // ?
43                              },
44                          };
45                      }
46  ...
```

To the spec!

```
1  /**
2   * The result of a hover request.
3   */
4  export interface Hover {
5    /**
6     * The hover's content
7     */
8    contents: MarkedString | MarkedString[] | MarkupContent;
9
10    /**
11     * An optional range is a range inside a text document
12     * that is used to visualize a hover, e.g. by changing the background color.
13     */
```

```typescript
14    range?: Range;
15  }
```

Let's not worry about that `range` parameter for now. Looking more closely at `contents`, let's dig into its variant `MarkupContent`:

```typescript
1   /**
2    * Describes the content type that a client supports in various
3    * result literals like `Hover`, `ParameterInfo` or `CompletionItem`.
4    *
5    * Please note that `MarkupKinds` must not start with a `$`. This kinds
6    * are reserved for internal usage.
7    */
8   export namespace MarkupKind {
9     /**
10     * Plain text is supported as a content format
11     */
12    export const PlainText: 'plaintext' = 'plaintext';
13
14     /**
15     * Markdown is supported as a content format
16     */
17    export const Markdown: 'markdown' = 'markdown';
18  }
19  export type MarkupKind = 'plaintext' | 'markdown';
20
21  ...
22
23  /**
24   * A `MarkupContent` literal represents a string value which content is
25   * interpreted base on its kind flag. Currently the protocol supports
26   * `plaintext` and `markdown` as markup kinds.
27   *
28   * If the kind is `markdown` then the value can contain fenced code blocks like
29   * in GitHub issues.
30   *
31   * Here is an example how such a string can be constructed using
32   * JavaScript / TypeScript:
33   * ```typescript
34   * let markdown: MarkdownContent = {
35   *  kind: MarkupKind.Markdown,
36   *  value: [
37   *    '# Header',
38   *    'Some text',
39   *    '```typescript',
40   *    'someCode();',
41   *    '```'
42   *  ].join('\n')
43   * };
44   * ```
45   *
46   * *Please Note* that clients might sanitize the return markdown. A client
         could
47   * decide to remove HTML from the markdown to avoid script execution.
48   */
49  export interface MarkupContent {
50    /**
51     * The type of the Markup
52     */
53    kind: MarkupKind;
54
55     /**
56     * The content itself
57     */
58    value: string;
```

```
59  }
```

Let's take advantage of this neat Markdown integration! All we really need to do is supply a `String` containing our Markdown content. Adding the appropriate code to our event loop, we can again use the types provided by `lsp_types` to create a `Hover` response. This struct is then serialized to transmit via RPC as our response object with our call to `serde_json::to_value()`. After that, we send it off!

```rust
1   /* src/main.rs */
2   if let Ok((id, params)) = cast_req::<HoverRequest>(req) {
3       if let Ok(word) =
4           get_word_from_file_params(&params.text_document_position_params)
5       {
6           let resp = match x86_instrs.get(&word) {
7               Some(instr) => {
8                   Some(Hover {
9                       contents: HoverContents::Markup(MarkupContent {
10                          kind: MarkupKind::Markdown,
11                          value: /* Documentation goes here... */,
12                      }),
13                  },
14              None => None,
15          };
16          let result = serde_json::to_value(&resp).unwrap();
17          let result = Response {
18              id: id.clone(),
19              result: Some(result),
20              error: None,
21          };
22          connection.sender.send(Message::Response(result))?;
23      }
24  ...
```

Just one issue, how do we get a Markdown string of our documentation? By implementing the `Display` trait of course! Let's make a brief stop by `src/instruction.rs`.

```rust
1   /* src/instruction.rs */
2   use std::fmt::Display;
3
4   use strum_macros::{AsRefStr, EnumString};
5
6   #[derive(Debug, Clone, Default)]
7   pub struct Instruction {
8       pub name: String,
9       pub summary: String,
10      pub arch: Option<Arch>,
11      pub forms: Vec<InstructionForm>,
12  }
13
14  impl Display for Instruction {
15      fn fmt(&self, f: &mut std::fmt::Formatter<'_>) -> std::fmt::Result {
16          let header: String;
17          if let Some(arch) = &self.arch {
```

28

```rust
18              header = format!("{} [{}]", &self.name, arch.as_ref());
19          } else {
20              header = self.name.clone();
21          }
22
23          let mut v: Vec<&str> = vec![&header, &self.summary, "\n", "##
    Forms", "\n"];
24
25          // instruction forms
26          let instruction_form_strs: Vec<String> =
27              self.forms.iter().map(|f| format!("{}", f)).collect();
28          for item in instruction_form_strs.iter() {
29              v.push(item.as_str());
30          }
31
32          let s = v.join("\n");
33          write!(f, "{}", s)?;
34          Ok(())
35      }
36 }
37
38 #[derive(Debug, Clone, Default)]
39 pub struct InstructionForm {
40      pub gas_name: Option<String>,
41      pub go_name: Option<String>,
42      pub encoding: String,
43      pub operands: Vec<Operand>,
44 }
45
46 impl Display for InstructionForm {
47      fn fmt(&self, f: &mut std::fmt::Formatter<'_>) -> std::fmt::
    Result {
48          let mut s = String::new();
49          if let Some(val) = &self.gas_name {
50              s += &format!("*GAS*: {} | ", val);
51          }
52          if let Some(val) = &self.go_name {
53              s += &format!("*GO*: {} | ", val);
54          }
55
56          // get rid of trailing " | "
57          if !s.is_empty() {
58              s = format!("- {}\n\n", &s[..s.len() - 3]);
59          }
60
61          // Operands
62          let operands_str: String = self
63              .operands
64              .iter()
65              .map(|op| {
66                  let mut s = format!("  + {:<8}", format!("[{}]", op.
    op_type.as_ref()));
67                  if let Some(input) = op.input {
```

29

```
68                     s += &format!(" input = {:<5} ", input)
69                 }
70                 if let Some(output) = op.output {
71                     s += &format!(" output = {:<5}", output)
72                 }
73
74                 s
75             })
76             .collect::<Vec<String>>()
77             .join("\n");
78         s = s + &operands_str + "\n";
79
80         write!(f, "{}", s)?;
81         Ok(())
82     }
83 }
```

Now that we've taken care of the `Display` trait, displaying our documentation is as simple as adding a single call to the `format!()` macro..

```
1  /* src/main.rs */
2  let resp = match x86_instrs.get(&word) {
3      Some(instr) => Some(Hover {
4          contents: HoverContents::Markup(MarkupContent {
5              kind: MarkupKind::Markdown,
6              value: format!("{}", instr),
7          }),
8          range: None,
9      }),
10     None => None,
11 };
```

Let's test it out!

3.0.5. Cleanup
